

Basal Cell Carcinoma - BCC

■ Electrosurgery of obvious tumor. The 5 year cure rate approach 92%

■ Primary excision is preferred for non-facial, well-defined nodular. The 5 year rate approach 90%

■ Mohs microsurgery is a highly specialized, tissue-sparing method of excision used for difficult tumors with contiguous growth. It is also used for recurrent BCC, histological aggressive forms of BCC, such as sclerotic BCCs, and tumors in anatomically important locations such as around eyes, nasal alar, mouth and ears.
